CRIME COIN OVERVIEW

Lets start by reviewing what i call “golden” crime. The coins I consider to fit the golden crime are, $MYX $COAI $RAVE $AIA $LAB $BEAT. These coins usually start between 0.3-0.4 and have a lockout trend up to 10-20$ within the span of a week or two.

These coins I’m very positive are all the same operator. They all follow an incredibly similar setup/playbook. Token ranges around 0.3 in price for weeks to months, usually 300 mil FDV, and if you view socials it is clearly a “ghost” project. You can tell no one is actually interested and the twitters are botted and the people doing twitter spaces and content are just random people, yet they tend to have VC raises by honestly quite a variety of VC’s but some recurring names bitget/maldstrom, hackVC.

These coins tend to get perps listing on binance first shortly followed by other notable CEX, and compared to other coins of the same volume, price and interest, OI is very obviously manipulated. They will do several shakeouts in the time leading up the “real pump” because they control almost the entire OI across all CEX so its very easy for them to use the “missing” oi not controlled by them and price movements in chart since there usually isnt spot listings for this right away to get basically tell when you are in or not, this part is assumed by me difficult to factual prove, but I have good confluence by this for shakes out seeming to not occur if i enter over a long period of time across multiple cex and or dex.

I monitor new CEX listings and cmc top 500 to stay alert for new projects (i’ve been slacking lately due to loss of interest and onchain pick up) that fit the bill similar tokenonics, weird socials, correct starting price, and volume and OI mismatches, compared to general sentiment of interest for the coin on social media. Then I just keep a watchlist of these coins, and usually wait for a some what convincing move which to me is a combination of the following.

1. A move above $1
2. Violent increase in OI that holds for longer than 12 hours. (it will usually double or triple within 1-6 hours after being relatively stagnant for weeks/months)
3. A shift into positive funding.
4. Large increase in OI specifically on aster or bitget by comparable markets. This can also be an early indicator, LAB had as much OI as ENA TAO ZEC and other highly traded alts on aster for around a week before it even started to move upward.
5, some sort of presale round and lockup, usually with a movable date, these can be found on echo or legion usually but not required for the set up. My suspected reasoning for this is this usually ends up sparking a lot of twitter talk as they do this close to the unlock and people naturally start talking about it, and then they change the unlock pretty close to the date. This also aligns as a method of distribution of wanting the general public to partake in the game of crash and funding yield after a certain price to further squeeze shorts they have a much better read on than anyone else due to the bundle on the OI, but it becomes risky to continue to inject funds past a certain point directly for them.
6. Wash trading onchain and similar lock up and distro platforms used, as well as activity on

bitget cold wallet is not really usable information for trading but frequent supply moves is a strong indicator its the correct group.
7. Usually after initial move above $1 and spike in funding into the positive, not too long after usually less than 48 hours, you want a strong move above $2.30 area and funding to start to dip deeply into the negative. To the point where it starts paying 1-2% of your position hourly, and will usually start to bait significant attention and algorithms trading this. From this point on anything above like 0.01% positive is very bad, you want funding to cycle between very negative and zero for the remain period of the coin but shifting into any sort of positive range is now bad, because usually strong indication too many late longs and people exiting shorts, its the best metric we have to try and read this even tho its not always the case.
8. You want to look for insanely obvious depegs in both perps price across CEX and onchain price vs CEX spot price. This in some form to my best guess is how they effectively can hold the funding at such ridiculous funding rates for large periods of time by doing something across the 99.99% bundle onchain and OI from the bottom they have. As well as CEX clearly being in on some degree, nance and bybit unlikely outside of just corruption to list, but bitget clearly has genuine involvement in many of these.

Basically this is a an overview of what I track and how I decide to enter and just hope they playout to a similar degree as the others, usually try to jump ship around $8 as im usually up a lot, and dont have the tools or the confidence to risk further funding farming or extracting.

To my knowledge a lot of these do set up in exactly this way but for whatever reason miss some sort of shorts threshold or other needed metrics to work and they kinda just drop them for dead. Examples $CYS $PIEVERSE $VELVET $POWER $BSB. (you can still profit off these, i made money off $BSB and $POWER just by being in very early with a small positive and trimming on the run up, just not a ton.

Altnerative types of crime. $SIREN $PIPPIN $JELLYJELLY $BANANAS31these are old memecoins that use to be real projects to some degree i suspect supply was accumulated in case of pippin and jellyjelly for months at a very low price due to preexisting cex listings for this crime, and in the case of siren purchased off the original team due to the large bundle. DWF is the operator confirmed for siren and likely the other two as well. These are much more random and hard to deal with usually have some association with gate io and large amounts of supply ending up there.

These are honestly somewhat readable with very good onchain tech because some wallets slip up and arent fresh and are involved with other coins, also you get wallets just DCA'ing in millions at certain levels over days as other wallets just basically sell and wash volume into those. Could suspect this is more aimed at laundering as DWF got in trouble w FEDs multiple times back in 2024, this only happens once the initial crime already started and its in the 100s of millions. Not much outside of gate supply control and random price increase to indicate crime.

But also failed examples of this exist like $SWARMS.

Other crime just really old coins like much holder than a year, that are usually between 20-50mil mc get accumulated and then squeezed hard its very difficult to tell with these because just like pippin and jellyjelly some of these use to be real projects that just get bought out over a long time frame, honestly i have a hard time sizing up on these and take frequent losses attempting to catch something similar, but these usually do the highest multiples out of all, these started to happen more frequently after i got a bit disinterested. But these I think are more similar to the golden crime batch where main gold bait and liquidate all shorts with a bundle. Need to research these a lot more tho.

Good Examples $STO $AKE
Failed example $JUNCTION
Suspected example given by guy at token $REZ

Also for “golden” crime the guy i met at token said $CT is good too, which looks entirely different set up from REZ which is also leads me to believe operators of golden crime prob run both related to liquidating shorts and profiting where as the old onchain coins run by DWF is money laundering scheme as well as profitable potentially?

Some notes about what me and my friend were doing a lot of this takes place natively on bnb chain so we basically my friend just had something that was pulling all current tx’s on the entire bnb chain and indexed the past tx’s and wallets on the coins of interest and then we tried training ai on analysing the data to give us something useful out of it
And we had bubble maps which i was able to shift thru more effectively manually than i would’ve normally and found a lot of weird things that are def telling to some degree but they didnt really give any insight as how to execute the actual trades, and it was getting really expensive and then i went on vacation for 2 weeks and then after i got back i just kinda stopped hearing from my friend regarding this and he stopped asking me for payments for the stuff so i just kinda figured he shut it down and moved on? Idk i didnt rly push much abt it other than just like two random mentions of some coins i wanted him to add i was pretty burnt out of pursuing this as well and happened to get burnt on a few back to back to back.

The best thing we actually build was just something to monitor OI and volume across all CEX and compare with aster, because some of the stuff just stands out super obviously on there, its just difficult to execute and not everything is on aster or uses it as part of crime so it isnt a catch all.

We were hoping to find patterns in wallet transfers and onchain wash trading like mm habits or algo giveaways, we didnt get deep enough into it, but im quite confident the data is there its just a matter of solving it.
